Cross-Sectional Comparative Assessment of Periodontal Status in Diabetic and Non-Diabetic Individuals Within a Romanian Cohort. Journal of Clinical Medicine (J. Clin. Abstract

Background/Objectives: Periodontitis and diabetes mellitus are known to exert a bidi rectional pathogenic influence characterized by metabolic dysregulation, exaggerated inflammatory response, and accelerated periodontal breakdown. Despite the increasing prevalence of both conditions in Eastern Europe, comparative clinical data from Romanian populations remain limited. This study aimed to assess differences in periodontal status, systemic comorbidities, smoking exposure, and local periodontal risk factors between diabetic and non-diabetic individuals in a Romanian cohort. Methods: This cross-sectional study included 345 adults (152 with diabetes; 193 non-diabetic individuals) all diagnosed with periodontitis. Although participants were recruited to achieve comparable distribu tions of sex and smoking status, individuals with diabetes were significantly

older than controls. Full-mouth periodontal examination was performed following the 2018 EFP/AAP classification criteria. Clinical parameters included probing pocket depth (PPD), clinical attachment level (CAL), plaque index (PI), and bleeding on probing (BOP). Periodon tal staging and grading were determined, and local risk factors were recorded using a multiple-response approach. Systemic comorbidities and smoking exposure were also evaluated. Statistical analyses involved t-tests, chi-squared tests, and Spearman correla tions; significance was set at $p < 0.05$. Results: Diabetic patients exhibited significantly higher mean PPD (4.33 ± 1.22 mm vs. 3.70 ± 0.86 mm; mean difference 0.63 mm, 95% CI: 0.45–0.81), greater CAL (mean difference 0.19 mm, 95% CI: 0.01–0.37), and elevated PI and BOP(PI meandifference 18.97%, 95% CI: 12.44–25.50; BOP mean difference 17.23%, 95% CI: 10.86–23.60). Advanced stages (III–IV) and Grade C periodontitis were more prevalent among diabetic individuals. Diabetic participants also presented a higher burden of local plaque-retentive factors and systemic comorbidities (notably hypertension and cardio vascular disease), as well as higher smoking intensity. Conclusions: Diabetes mellitus is associated with markedly poorer periodontal status, greater systemic disease burden, and increased prevalence of plaque-retentive local factors. These findings reinforce the bidirectional relationship between diabetes and periodontitis and support the integration of periodontal assessment into metabolic disease management protocols.

Determinants of Oral Health Outcomes and Quality of Life in Diabetic Patients from Western Romania: A Behavioral Model Approach. Dentistry Journal (Dent. J.), 2025, 13, article no. 247. DOI: 10.3390/dj13060247. Impact Factor (JIF, 2024): 3.1 (JCR; Q1).

Abstract

Background/Objectives: Oral health and diabetes are closely linked through shared inflammatory, behavioral, and socioeconomic factors. This study examined the determinants of oral health outcomes and oral-health-related quality of life (OHRQoL) in Romanian diabetic patients using Andersen's Behavioral Model. Methods: A cross- sectional study was conducted in early 2025 among 79 diabetic patients at a public clinic in Western Romania. Data were collected through questionnaires, clinical oral exams, and the OHIP-14 instrument. Variables were analyzed using Andersen's Behavioral Model and standard statistical tests, including regression and correlation analyses. Results: Participants had a mean age of 61.2 years; 86.1% had type 2 diabetes and 13.9% type 1. Over 49%reportedgingivalbleeding, and38%experienceddentalsensitivity.

Regressionanalysis identified limited awareness (OR = 2.21, p = 0.033) and low income (OR = 1.89, p = 0.041) as significant predictors of periodontal symptoms. OHIP-14 scores were weakly correlated with glycemic control (r = 0.17) and dental sensitivity (r = 0.16) but not with objective periodontal parameters. Rural residence, lower education levels, and poor awareness were associated with reduced service utilization and poorer perceived oral health. Conclusions: This study highlights the impact of behavioral, clinical, and socioeconomic factors on oral condition and OHRQoL. Oral health should be integrated into chronic disease care, with prevention-focused strategies aimed at improving access and reducing disparities, especially in older and rural populations

Abstract

T2DM mellitus (T2DM) is a major global health issue associated with significant morbidity, mortality, and economic burden. While the role of lifestyle fac tors in glycemic control is well-established, the influence of oral health behaviors remains underexplored. Objective: This study aimed to investigate the interplay between lifestyle habits, oral health behaviors, and glycemic control in patients with T2DM. Methodology: A cross-sectional study was conducted on 132 patients (66 men and 66 women) with T2DM at the Pius Brînzeu Emergency Hospital in Timis ,oara, Romania. Data on smoking, physical activity, alcohol consumption, tooth brushing frequency, and dental visits were collected using structured questionnaires, and glycemic control was assessed through HbA1c mea surements. Statistical analyses, including Pearson correlations and linear regression, were performed. Results: Among men, HbA1c levels were negatively associated with exercise frequency (ß = −0.26, $p < 0.05$) and education level (correlation coefficient −0.27, $p < 0.05$), and positively associated with dental visits and tooth brushing frequency (correlation coefficient 0.26, $p < 0.05$). In the combined analysis, education level positively correlated with both dental visits (correlation coefficient 0.24, $p < 0.01$) and alcohol consumption (cor relation coefficient 0.22, $p < 0.05$). Conclusions: These findings underscore the importance of integrating oral health and lifestyle interventions into diabetes management to optimize patient outcomes

Total antioxidant capacity of saliva and its correlation with pH levels among dental students under different stressful conditions. Diagnostics. 2023;13(24):3648. doi:10.3390/diagnostics13243648.

Abstract:

This cross-sectional study conducted at the Faculty of Dental Medicine, Timisoara, Romania, between December 2022 and February 2023 aims to assess salivary total antioxidant capacity and pH levels in dental students experiencing non-stressful and stressful situations and explore potential correlations between these factors. (2) Methods: Saliva samples were collected during two different periods: before an Oral Health course and before the Oral Health exam, under stressful conditions. Ethical principles were followed, and informed consent was obtained. Data on age, gender, health status, drug use, smoking habits, and anxiety levels were recorded. Saliva was collected using the draining method and pH was measured using indicator paper strips. Total antioxidant capacity (TAC) was determined using a commercial assay kit. Statistical analysis involved descriptive statistics, Student's *t*-test to compare pH and TAC between study groups, and Pearson's correlation coefficient to analyze the correlation between salivary pH and TAC within each group, with $p < 0.05$ indicating significance. (3) Results: This study involved 80 participants, comprising 26 males and 54 females, all enrolled in the 5th year of the Oral Health course, with ages ranging from 20 to 53 and a mean age of 23.62 (±4.19) years. Pearson's correlation results show a statistically significant negative relationship between the STAI test and TAC during the stress-free period (−0.02 **, $N = 80$, $p < 0.01$). (4) Conclusions: There are variations in saliva's antioxidant capacity in response to different stress conditions. Dental students experienced a higher level of stress before academic assessments compared to the non-stress period during the course.

Romanian Journal of Oral Rehabilitation, 2025, 17(2), April–June. DOI: 10.62610/RJOR.2025.2.17.88.

Abstract

Aim of the study The objective of this study was to investigate the bidirectional relationship between diabetes mellitus and periodontal disease, in the context of systemic comorbidities and multimorbidity. Materials and methods This cross-sectional observational study analyzed a cohort of 254 patients diagnosed with periodontal disease, divided into three groups: patients without systemic conditions (controls), patients with diabetes mellitus as the primary comorbidity, and patients with multimorbidity (diabetes associated with at least one other chronic condition such as cardiovascular, hepatic, or metabolic disease). The main clinical parameters assessed were probing depth (PD), plaque index (PI), and bleeding on probing (BOP). Normality was tested using the Shapiro Wilk test, and intergroup differences were analyzed via the non-parametric Kruskal-Walli's test. Results Statistically significant differences were found for probing depth ($p = 0.003$) and plaque index ($p < 0.001$), with the most severe values observed in diabetic and multimorbid patients compared to the control group. Bleeding on probing did not reach statistical significance ($p = 0.069$), but was clinically elevated, reflecting the persistent inflammatory status characteristic of chronic periodontitis. Conclusions Diabetes mellitus is associated with more advanced periodontal destruction, and this association is further accentuated when accompanied by additional systemic diseases. These findings support the existence of a bidirectional relationship between diabetes and periodontal disease, highlighting the relevance of integrated care in the context of multimorbidity.

Abstract

Background/Objectives: Diabetes mellitus (DM) is a chronic, non-communicable disease with significant systemic and oral health complications. Early, non-invasive diagnostic approaches, such as salivary biomarker analysis, could improve management and reduce associated complications. Salivary alpha-amylase has emerged as a promising biomarker due to its role in glycemic control and stress-related sympathetic activation. This study aims to evaluate salivary

alpha-amylase levels as potential biomarkers for type 2 diabetes mellitus (T2DM) and explore their correlation with clinical parameters.2. Methods: A cross-sectional study was conducted involving 40 participants (20 T2DM patients and 20 controls). Saliva samples were collected and analyzed for alpha-amylase using ELISA. Data on oral health, body mass index (BMI), glycated hemoglobin (HbA1c), and total cholesterol were also collected.3. Results: Salivary alpha-amylase levels were significantly higher in T2DM patients (mean: 177.86 μ/L) compared to controls (mean: 90.98 μ/L, p = 0.001). Poorer oral health, higher BMI, and increased cholesterol levels were observed in diabetic participants. HbA1c levels revealed suboptimal glycemic control in a subset of patients.4. Conclusions: Salivary alpha-amylase shows potential as a non-invasive biomarker for T2DM diagnosis and monitoring. The findings emphasize the need for integrated medical and dental management to address systemic and oral health challenges in diabetes. Further research is needed to validate and standardize salivary diagnostic methodologies

Systemic correlations of the oral microbiome and salivary parameters in smoking patients. Medicine in Evolution. 2023;29(3):350. ISSN 2065-376X. Available from: http://medinevolution.umft.ro/2023/medinevol_3_2023.pdf

Abstract

The oral microbiome is intricately linked to human health and systemic diseases, with smoking being a prevalent risk factor. This meta-analysis aimed to investigate the impact of smoking on salivary parameters in individuals aged 20-55 without systemic diseases who exclusively smoked traditional cigarettes. Ethical approvals were not necessary as existing data from English-language publications between 2021-2022 were used. The analysis included 33 studies with 2813 participants (1392 smokers and 1421 non-smokers). The primary focus was on salivary pH changes in smokers compared to controls, with varied collection methods and restrictions. Additionally, 10 studies assessed total salivary antioxidant capacity in both groups. The results revealed lower salivary flow in smokers, while salivary antioxidant capacity varied. Overall, smoking emerged as a significant public health concern in the EU, contributing to high mortality rates. The findings demonstrate that smoking is associated with decreased salivary pH, reduced salivary flow, and lower total salivary antioxidant capacity, potentially leading to oral mucosal and dental problems and an increased risk of periodontal disease and premalignant lesions.
